

Impact Jetting and the Origin of Ordinary Chondrites

Yasuhiro Hasegawa
(Jet Propulsion Laboratory,
California Institute of Technology)

JPL: Neal Turner, Joseph Masiero
CfCA/NAOJ: Shigeru Wakita,
Yuji Matsumoto, Shoichi Oshino

Chondrules: the primitive material formed in the Solar Nebula (disk)

abundant in chondrites
(up to 80 % by volume)

~1 mm sized spherical particles
formed as molten droplets
of silicate ($T \sim 1800\text{K}$)

the cooling rate is
~ 10 - 1000 K per hour
(the nebular gas is needed)

kept forming for 3-5 Myr
after CAI formation began,
which is 4.567 Gyr ago

cf) Mars formed at ~2 Myr after CAI formation

New information from lab experiments : magnetic fields in the nebula (disk)

Fu et al 2014

Semarkona meteorite
: primitive, ordinary chondrite

Both thermoremanent
magnetization & its direction
=> olivine-bearing chondrules
were likely magnetized
in the solar nebula

B-fields in the solar nebula were $\sim 50 - 540$ mG
=> Level of turbulence in the nebula can be estimated!!

B-fields

Key idea: impact jetting

e.g., Johnson et al 2015

simulated by iSALE

A planetesimal with $r = 5\text{km}$ collides with a planetesimal or a protoplanet

Some materials melt, and are ejected from the system

Such ejected materials can be a progenitor of chondrules

Wakita et al 2017

Total ejected mass is about 1% of impactors' mass when $v > 2.5 \text{ km/s}$

Lots of collisions occur when protoplanets form

Hasegawa et al 2016a

Protoplanets form via runaway/oligarchic growth

Impact velocity of 2.5 km/s is achieved in the oligarchic phase

Chondrule-forming collisions occur at the hatched region

The total chondrule abundance is 1 % of the protoplanet mass

MMSN = the Minimum Mass of the Solar Nebula

Lots of collisions occur
when protoplanets form

Hasegawa et al 2016a

Protoplanets form via

Both the resulting abundance and the formation timescale
of chondrules seem reasonable!!

(Note that the thermal history of chondrules may also be fine)

Chondrule-forming collisions
occur at the hatched region

The total chondrule abundance
is 1 % of the protoplanet mass

MMSN =
the Minimum Mass of the Solar Nebula

B-fields

Lab results (magnetic fields) come into play!!!

B-fields

Lab results (magnetic fields) come into play!!!

B-fields

MagnetoRotational Instability (MRI) can operate

Disks become turbulent

Flock et al 2011

Lab results (magnetic fields) come into play!!!

h depends on level of turbulence,
so the B-field strength

B-fields

MagnetoRotational Instability (MRI) can operate

Disks become turbulent

Chondrules

Flock et al 2011

H increases with disk mass and planetesimal mass (protoplanet)

Chondrule accretion onto planetesimals

occurs when $H < h$

Lesion et al 2015

h increases with vertical magnetic flux

H increases with disk mass and planetesimal mass (protoplanet)

B-fields (mG) Chondrule mass (g)

Disk mass (MMSN)

B-fields (mG) Chondrule mass (g)

A large number of chondrules form in massive disks

Disk mass (MMSN)

No chondrule formation due to a low disk mass

B-fields (mG) Chondrule mass (g)

Disk mass (MMSN)

A large number of chondrules form in massive disks

A very strong magnetic field is needed for chondrules to have the same height as planetesimals

Planetesimals can reside in the chondrule sea, but no chondrules indeed

No chondrule formation due to a low disk mass

All the currently available meteorite data can be satisfied
 when the disk mass is $< 5 \text{ MMSN}$

the planetesimal mass is $< 10^{24} \text{ g}$

Hasegawa et al 2016b

Planetesimal mass

Our model needs a first generation of planetesimals
that trigger impact jetting and
serve as parent bodies to accrete chondrules

cf) Mars formed at ~2 Myr after CAI formation

Next Step

Planetesimal Formation & Origins of Asteroids

Scenario 1: Chondrule accretion

Hasegawa et al 2016b, Matsumoto et al 2017

OSIRIS-REx

Scenario 2: Chondrule accumulation

Hasegawa et al 2017 in prep

Hayabusa 2

We will **identify** formation mechanism(s) of planetesimals

Summary

Hasegawa et al 2016a, ApJ, 816, 9

Hasegawa et al 2016b, ApJ, 820, L12

Wakita et al 2017, ApJ, 834, 125

Matsumoto et al 2017, ApJ, 837, 103

- Primitive meteorites contain fossil records of the solar system
- Coupling of impact jetting with subsequent chondrule accretion is a promising scenario to account for the currently available meteorite data
- all the requirements can be met when the disk mass is $<$ about 5 MMSN and the planetesimal mass is $<$ about 10^{24} g
- Our model implies that only primordial asteroids that were originally smaller than 500 km in radius may have a chondrule-rich surface layer (~ 0.3 km)!!
- The upper limit of the planetesimal mass is comparable to that of Vesta/Ceres, and current observations/missions may provide an invaluable opportunity to verify our scenario!!

Summary

Hasegawa et al 2016a, ApJ, 816, 9

Hasegawa et al 2016b, ApJ, 820, L12

Wakita et al 2017, ApJ, 834, 125

Matsumoto et al 2017, ApJ, 837, 103

- Primitive meteorites contain fossil records of the solar system
- Coupling of impact jetting with subsequent chondrule accretion is a promising scenario to account for the currently available meteorite data
- all the requirements can be met when the disk mass is $<$ about 5 MMSN and the planetesimal mass is $<$ about 10^{24} g

- I(We) need to know chondrules more
 - Planetesimal collisions and the resulting impact jetting may be effective only for CB chondrites??
 - It is important to examine a number of chondrule-forming mechanisms in the single framework
- an invaluable opportunity to verify our scenario!!
